Chapter 8 - Functional Parsers

What is a Parser?

A parser is a program that analyses a piece of text to determine its syntactic structure.

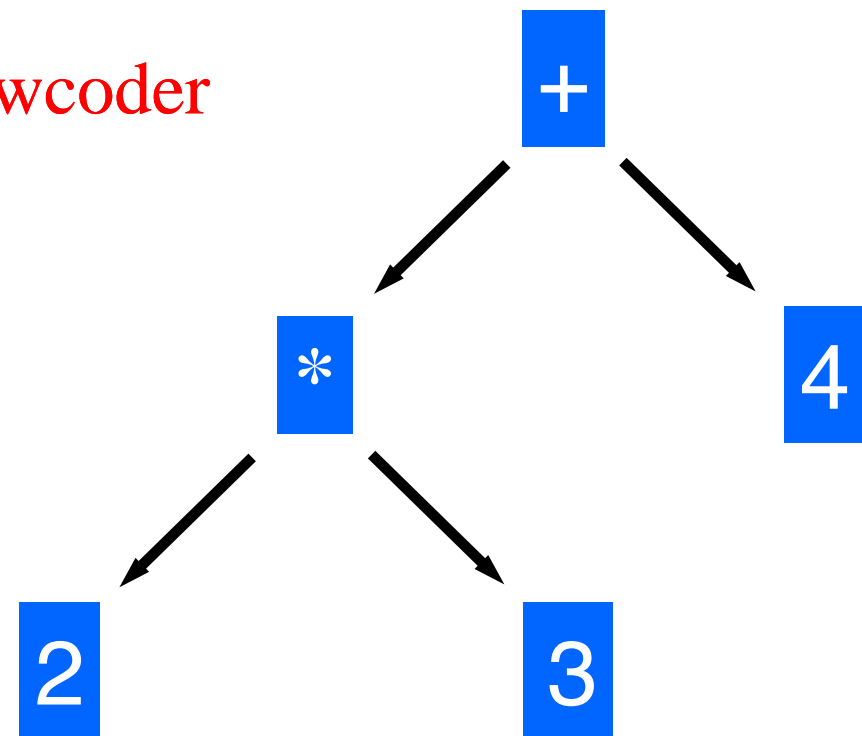

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

2*3+4

means

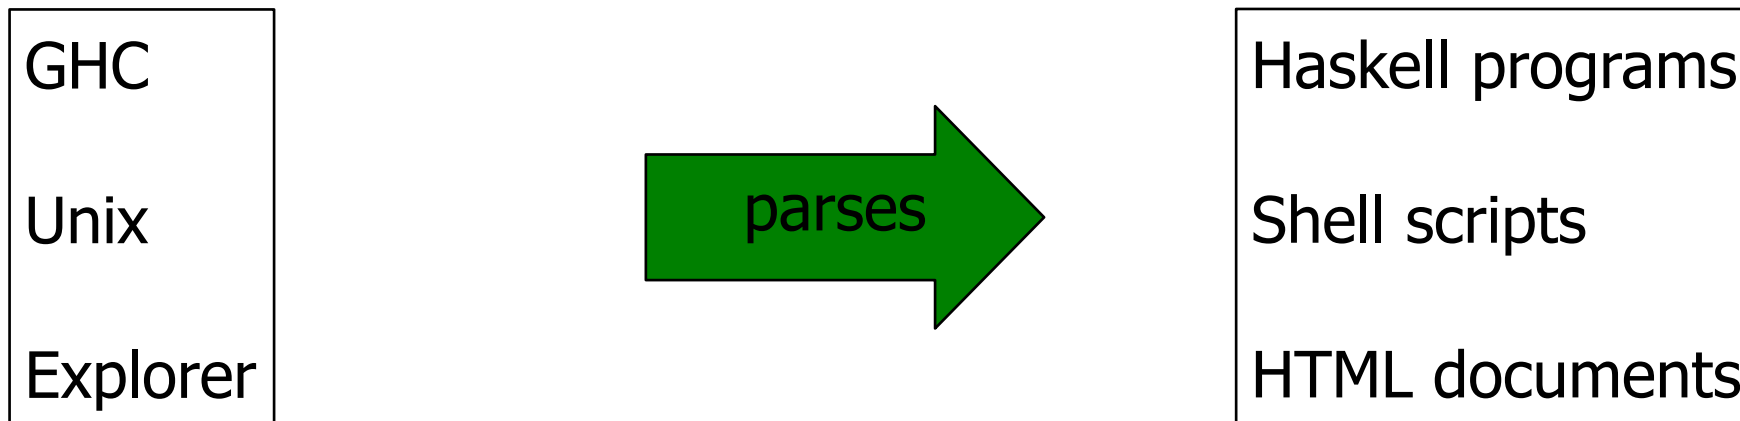

Where Are They Used?

Almost every real life program uses some form of parser to pre-process its input.

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

The Parser Type

In a functional language such as Haskell, parsers can naturally be viewed as functions.

Assignment Project Exam Help

<https://powcoder.com>

data Parser = P (String → Tree)

A parser is a function that takes a string and returns some form of tree.

However, a parser might not require all of its input string, so we also return any unused input:

```
data Parser = P (String → (Tree,String))
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

A string might be parsable in many ways, including none, so we generalize to a list of results:

```
data Parser = P (String → [(Tree,String)])
```

Finally, a parser might not always produce a tree, so we generalize to a value of any type:

```
data Parser a = P (String → [(a,String)])
```

Assignment Project Exam Help

<https://powcoder.com>

Note:

Add WeChat powcoder

- ❓ For simplicity, we will only consider parsers that either fail and return the empty list of results, or succeed and return a singleton list.

Basic Parsers

- ❓ The parser item fails if the input is empty, and consumes the first character otherwise:

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
item :: Parser Char
```

```
item = P ( $\lambda$ inp  $\rightarrow$  ?)
```

? The parser failure always fails:

```
failure :: Parser a  
failure = P ( $\lambda$ inp  $\rightarrow$  ?)
```

Assignment Project Exam Help

<https://powcoder.com>

? The parser return v always succeeds, returning the value v without consuming any input:

Add WeChat powcoder

```
return :: a  $\rightarrow$  Parser a  
return v = P ( $\lambda$ inp  $\rightarrow$  ?)
```

- ? The parser $p \text{ +++ } q$ behaves as the parser p if p succeeds, and as the parser q otherwise:

$(+++)$:: Parser $a \rightarrow$ Parser $a \rightarrow$ Parser a
 $p \text{ +++ } q = P (\lambda \text{inp} \rightarrow ?)$

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

- ? The function parse applies a parser to a string:

$\text{parse} :: \text{Parser } a \rightarrow \text{String} \rightarrow [(a, \text{String})]$
 $\text{parse } (P \text{ } p) \text{ inp} = p \text{ inp}$

Examples

The behavior of the five parsing primitives can be illustrated with some simple examples:

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
% ghci Parsing
```

```
> parse item ""
```

```
[]
```

```
> parse item "abc"
```

```
[('a',"bc")]
```

```
> parse failure "abc"
```

```
[]
```

```
> parse (return 1) "abc"
```

```
[(1,"abc")]
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
> parse (item +++ return 'd') "abc"
```

```
[('a',"bc")]
```

```
> parse (failure +++ return 'd') "abc"
```

```
[('d',"abc")]
```

Note:

- ❓ The library file Parsing will be available on the web from Moodle.
- ❓ For technical reasons, the first failure example actually gives an error concerning types, but this does not occur in non-trivial examples.

Assignment Project Exam Help

- ❓ The Parser type is a monad, a mathematical structure that has proved useful for modeling many different kinds of computations.

<https://powcoder.com>
Add WeChat powcoder

Sequencing

A sequence of parsers can be combined as a single composite parser using the keyword do.

For example:

Assignment Project Exam Help

```
p :: Parser (Char,Char)
p = do x <- item
      item
      y <- item
      return (x,y)
```

<https://powcoder.com>

Add WeChat powcoder

Sequencing

The do-notation allows you to take what you parsed from the Parser structure!

Later in the course we will explain how this works.

Assignment Project Exam Help

```
p :: Parser (Char,Char)
```

```
p = do x ← item
```

```
    item
```

```
    y ← item
```

```
    return (x,y)
```

<https://powcoder.com>

Add WeChat powcoder

item :: Parser Char

x :: Char

Note:

- ❓ Each parser must begin in precisely the same column. That is, the layout rule applies.
- ❓ The values returned by intermediate parsers are discarded by default, but if required can be named using the \leftarrow operator.
- ❓ The value returned by the last parser is the value returned by the sequence as a whole.

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

- ? If any parser in a sequence of parsers fails, then the sequence as a whole fails.
For example:

```
> parse p "abcdef"
```

```
[(('a','c'),"def")]
```

```
> parse p "ab"
```

```
[]
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

- ? The do notation is not specific to the Parser type, but can be used with any monadic type.

Derived Primitives

 Parsing a character that satisfies a predicate:

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
sat :: (Char → Bool) → Parser Char
sat p = ?
```

? Parsing a digit and specific characters:

```
digit :: Parser Char
```

```
digit = sat isDigit
```

```
char :: Char → Parser Char
```

```
char x = ?
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

? Applying a parser zero or more times:

```
many :: Parser a → Parser [a]
```

```
many p = many1 p +++ return []
```

? Applying a parser one or more times:

```
many1 :: Parser a -> Parser [a]
many1 p = ?
```

Assignment Project Exam Help

? Parsing a specific string of characters: <https://powcoder.com>
Add WeChat powcoder

```
string :: String -> Parser String
string = ?
```

Example

We can now define a parser that consumes a list of one or more digits from a string:

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
p :: Parser String
p = do char '['
      d ← digit
      ds ← many (do char ','
                    digit)
      char ']'
      return (d:ds)
```

For example:

```
> parse p "[1,2,3,4]"  
[("1234","")]
```

```
> parse p "[1,2,3,4"  
[]
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Note:

- ❓ More sophisticated parsing libraries can indicate and/or recover from errors in the input string.

Arithmetic Expressions

Consider a simple form of expressions built up from single digits using the operations of addition $+$ and multiplication $*$, together with parentheses.

Assignment Project Exam Help

We also assume that:

<https://powcoder.com>

Add WeChat powcoder

 $*$ and $+$ associate to the right;

 $*$ has higher priority than $+$.

Formally, the syntax of such expressions is defined by the following context free grammar:

$expr \rightarrow term '+' expr \mid term$

$term \rightarrow factor '*' term \mid factor$

$factor \rightarrow digit \mid '(' expr ')'$

$digit \rightarrow '0' \mid '1' \mid \dots \mid '9'$

However, for reasons of efficiency, it is important to factorise the rules for *expr* and *term*:

$expr \rightarrow term \mid '+' expr \mid \varepsilon$

Assignment Project Exam Help

$term \rightarrow factor \mid '-' term \mid \varepsilon$

<https://powcoder.com>
Add WeChat powcoder

Note:

 The symbol ε denotes the empty string.

It is now easy to translate the grammar into a parser that evaluates expressions, by simply rewriting the grammar rules using the parsing primitives.

That is, we have:

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
expr :: Parser Int
expr = ?
```

```
term :: Parser Int  
term = ?
```

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

```
factor :: Parser Int  
factor = ?
```

Finally, if we define

```
eval  :: String → Int
eval xs = fst (head (parse expr xs))
```

Assignment Project Exam Help

then we try out some examples:

<https://powcoder.com>

Add WeChat powcoder

```
> eval "2*3+4"
10
```

```
> eval "2*(3+4)"
14
```

Exercises

- (1) Why does factorising the expression grammar make the resulting parser more efficient?

- (2) Extend the expression parser to allow the use of subtraction and division, based upon the following extensions to the grammar.

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

$$expr \rightarrow term \mid '+' expr \mid '-' expr \mid \varepsilon$$
$$term \rightarrow factor \mid '*' term \mid '/' term \mid \varepsilon$$
